Marrying Up, Messaging Up, Making It Up: Where Hypergamy Is Real, Half Real and Not Real

Umay Şamlı

samliumay965@gmail.com

***Abstract*—Online, "hypergamy" is used as a law of nature: women always marry up, and most of them chase the top 20% of men. In the research literature the word covers at least four separate claims, and the evidence differs for each. We sort published findings by claim. On average, women in almost every country studied say a partner's earning prospects matter more to them than men say, but the gap is small on any single trait, and both sexes rank kindness and intelligence higher. Once people meet face to face, earning prospects predict attraction only weakly, and about equally for both sexes. Women marrying up in education was the norm for most of the twentieth century and has now reversed in most countries; models show that the reversal follows the supply of educated men and women, with no change in preferences needed. Women still tend to partner with men who earn more and who are a few years older. The "80/20" claim is not supported: attention on dating sites is unequal, but men and women aim above themselves by about the same amount, and most couples match like with like. Beyond status, women's stronger interest in a partner's status is mostly a long-term preference: for casual partners both sexes put looks first, and the claimed shifts in women's taste around ovulation have not held up in large preregistered studies. Height, build, penis size and intelligence count in ratings, mostly by small amounts, and couples resemble each other in height and intelligence. Most of the famous dating-app numbers, such as the "Gini of likes", come from blogs and press stories. Racial hierarchies on dating sites are well documented, and we treat them as discrimination. We close with the Hypergamy Meter, a desktop toy whose hand-picked weights make it a joke, not a measurement. It leaves ethnicity out on purpose.**

***Index Terms*—hypergamy, assortative mating, mate preferences, online dating, educational hypogamy, satire**

I. Introduction

Ask the internet whether hypergamy is real and you will be told, with great confidence, that it is the master key to modern dating. In this version, women only ever partner with men above them, status is all that matters, and a small elite of men gets most of the attention while everyone else is left out.

Sociology and psychology use the word more narrowly. Hypergamy usually means a pattern in couples: the woman's partner ranks above her on some dimension, such as education [1], [2]. Mate-preference research asks a separate question, namely what people *say* they want [3], [4], and dating research asks a third: whom people actually contact, like and marry [5]–[7]. Online arguments slide between these, so evidence for one claim gets passed off as proof of another.

This paper sorts the claims and checks each one against the evidence. It is a side project and it has a joke app attached (Section VI), but the review is meant to be accurate. Our contributions are:

- a split of "hypergamy" into four claims, each with the kind of data that could support it (Fig. 1);
- a verdict for each claim, graded by strength of evidence (Table I);
- a short account of the three main explanations, including a supply-based model in which hypergamy appears and then reverses without anyone's preferences changing [8];
- a second verdict table for claims beyond status (Table II) and an evidence grade for each famous dating-app number (Table III);
- a description of the Hypergamy Meter, and a plain statement of why its output means nothing.

II. Four Meanings of "Hypergamy"

Fig. 1 shows the four meanings we use throughout.

D1, partnering up. In a couple, the man ranks above the woman on education, income, occupation, class or age. The evidence is the share of couples in which he is higher, compared with what random pairing would give, and it comes from censuses, registers and couple surveys.

D2, stated preference. Women say they weigh a partner's status or earnings more than men do. The evidence is questionnaire ratings.

D3, revealed preference and actual matching. Whom people contact, reply to, swipe on, date and marry. The evidence is dating-site logs, speed dating, field experiments and marriage records.

D4, the strong online claim. Most women pursue a small top fraction of men ("80/20"), and status is all that matters. The evidence would have to show that both attention and actual partnering are concentrated on a few men.

None of these implies another. D1 can appear even when nobody prefers it, because of who is available (Section V), and a stated preference (D2) may say little about whom people end up liking (D3) [5], [9]. Attention on an app (D3, first contact) is not the same thing as who ends up in a couple (D4 is about both).

III. Evidence by Claim

Table I summarises the verdicts. *Strong* means several large or representative studies or meta-analyses agree; *moderate* means good studies with some disagreement or limited settings; *weak* means small, local, grey or unreplicated work.

TABLE I
VERDICT TABLE: ● EXISTS, ◐ PARTLY, ○ DOES NOT EXIST (AS STATED), ? UNCLEAR.

Claim	Def.		Verdict	Strength	Main sources
Women, on average, *say* earning prospects matter more than men say	D2	●	exists, in nearly every country studied	strong	[3], [4], [10], [11]
That stated difference is large	D2	◐	small per trait, large only when many traits are combined	strong	[4], [10]
Both sexes rank kindness and intelligence above money and looks	D2	●	exists	strong	[3], [4]
The stated sex difference shrinks with gender equality	D2	?	some studies yes; largest replications no, except for age gaps	moderate	[4], [11]–[13]
Stated status preferences predict in-person attraction, more for women	D2→D3	○	mostly not: weak for both sexes, no reliable sex difference	strong (contested)	[5], [9]
When screening profiles online, women weight a man's education or income more	D3	●	exists	moderate	[14]–[16]
Women marry up in education	D1	◐	historically yes; now reversed in most countries	strong	[1], [2], [17], [18]
Educational hypergamy reflected a wish to marry up	D1	○	not needed: supply plus a taste for similarity reproduces it	moderate (model)	[8], [19]
Women partner with men who earn more	D1	●	exists, and persists after the education reversal	strong	[18], [20]
That income gap shows women's preference for higher earners	D1	◐	mixed with pay gap, selection and men's choices	moderate	[20]–[22]
A breadwinner norm shows as a drop where wives start to out-earn husbands	D1	?	the drop exists; its reading is contested	moderate	[23]–[26]
Women partner with older men	D1	●	about 2 to 3 years on average	strong	[4], [27], [28]
Marriages where she "married down" are less stable	D1	○	not in recent US cohorts	moderate	[17], [29]
Women trade beauty for men's status	D1	?	much apparent exchange is like-with-like matching	moderate	[30]–[32]
Aiming above oneself is a female trait	D3	○	both sexes aim up by similar amounts	strong	[6], [33]
Attention on dating apps is unequal; men get fewer replies	D3	●	exists	moderate	[6], [33], [34]
Most women chase the top ∼20% of men, leaving most men out	D4	○	not supported as stated	moderate	[6], [33], [35]
Some groups of women face fewer "marriageable" men	D1	●	exists for some groups and places	moderate to strong	[22], [36], [37]
Same-sex couples show the same status patterns	D1	?	thin evidence; less homogamy overall	weak to moderate	[38]–[40]

A. Stated Preferences (D2)

Buss surveyed 37 samples in 33 countries ($N = 10{,}047$) [3]. In most samples women rated "good financial prospects" and ambition higher than men did, and men rated youth and looks higher. A pre-planned replication in 45 countries ($N = 14{,}399$) found the same direction [4]. On a 1 to 7 scale, women rated financial prospects about 0.30 points higher than men, and men rated physical attractiveness about 0.27 points higher. Both sexes rated kindness, intelligence and health above money and looks.

Whether that is a big difference depends on how you count. Per trait, it is small. Across all 18 items of the 1989 data the multivariate distance is $D = 2.41$, about 22.8% overlap, and sex can be predicted from a person's preference profile with 92.2% accuracy [10]. Across five items in the 2020 data it is $D = 0.73$ [4]. Multivariate distances grow with the number of items, so an honest report gives both: single traits overlap heavily, while whole profiles differ more.

Does the gap shrink where women have more equality? Some studies say yes [12], [13], as social role theory predicts [41], [42]. The largest and most careful replications found little moderation except for age gaps [4], [11], and neighbouring countries are not independent data points [43]. The difference appears in every country studied. Whether equality shrinks it is still open.

B. Stated Versus Revealed Preferences (D2 to D3)

In speed dating, the stated sex difference in caring about earning prospects did not predict whom people liked after meeting [9]. A meta-analysis of 97 studies reports that attractiveness predicts romantic evaluations at about $r = .40$ and earning prospects at about $r = .10$ for *both* sexes, with a sex difference near .03 [5]. Critics say this covers early attraction and existing couples rather than long-term choice from a wide pool, so the debate continues.

At first contact the difference comes back. Women on a US dating site weighted a man's income more than men weighted a woman's [14]. In a Tinder field experiment in Belgium (24 fake profiles, 3,600 evaluations), women strongly preferred highly educated men, while men showed neither a preference for nor an aversion to highly educated women [15]. In speed dating, men did not value a woman's intelligence or ambition when it exceeded their own [21], a male-side asymmetry that

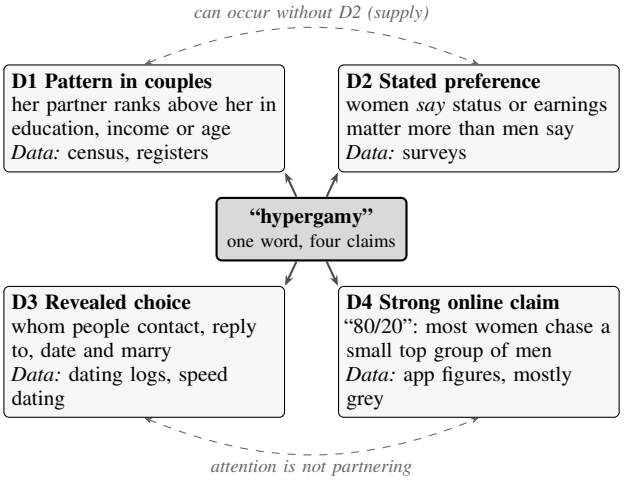

Fig. 1. The four meanings of "hypergamy" used in this paper. Evidence for one is not evidence for another: D1 can arise from supply alone, D2 predicts D3 weakly once people meet, and attention on an app (D3, D4) is not partnering.

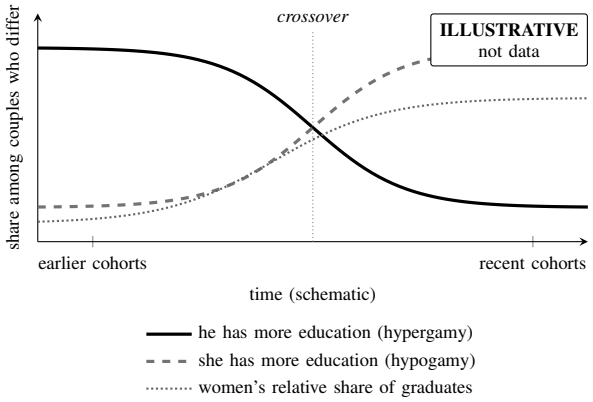

Fig. 2. Schematic of educational hypergamy reversing as women's education overtakes men's. *Illustrative only*: the curves are drawn by hand and contain no data. The direction of change follows [1], [2], [17], [18]. Timing and size vary by country.

also produces "hypergamous" couples. So status counts for more in screening and for much less once people actually meet.

C. Actual Matching: Education (D1)

The strongest pattern in marriage data is like marrying like. US educational homogamy rose from 1960 to 2003 [44], and sorting on similarity runs through partner choice in general [45].

Educational hypergamy did exist: for most of the twentieth century, when spouses differed, he usually had more schooling. That pattern has reversed. Census data from 56 countries show a near-universal decline [1], and 420 samples from 120 countries (1960 to 2011) link the end of hypergamy to women overtaking men in education [2]. In Western countries, couples in which the wife has more education now outnumber those in which the husband does [17]. In the US, newlyweds moved from women marrying up (1980) to women marrying down (2008 to 2012) [18]. In Europe, highly educated women more often partnered with less educated men instead of staying single, and low-educated men more often stayed single [19]. Fig. 2 sketches the shape of this change.

Two follow-ups matter for the online story. Marriages in which the wife had more education used to be more likely to end, but in recent US cohorts that link has gone [29]. And where a strong norm meets a changing supply, marriage can fall instead: in Japan, fewer highly educated women marry, which is linked to a shortage of men with the education and earnings they and the local norms expect [37].

D. Actual Matching: Income (D1)

Income hypergamy outlived educational hypergamy. In the US, women's tendency to marry men with higher incomes persisted from 1980 to 2008–2012, and was *stronger* when the wife was as educated as her husband or more [18]. In Swedish register data, women in education-hypogamous couples had higher class background and occupational prestige than their partners but lower income, partly because lower-earning people select into such couples [20]. A partner who is "up" on one dimension is often "down" on another. Spouses' earnings have also become more alike over time, which is like-with-like again [46].

The shortage side is real too. The men that unmarried US women would be expected to marry, constructed from the husbands of comparable married women, earn about 58% more than the unmarried men actually available and are more often employed (90% vs. 70%) [36]. When manufacturing declined, young men's earnings fell relative to women's and marriage fell with them [22].

The best-known "proof" online is a sharp drop in the number of US couples just past the point where the wife out-earns the husband, read as a male-breadwinner norm [23]. Later work shows that matching models with no norm reproduce the distribution and that the drop comes from couples with exactly equal earnings [24]. In Finland it comes from co-working spouses whose earnings converge [25], and a replication, not yet peer reviewed, finds the labour-force result turns to zero with hourly wages [26]. The norm may exist, but this evidence does not settle it.

E. Actual Matching: Age (D1)

Age is the most stable finding. Women prefer and marry slightly older men at all ages, and men's preference for younger women grows as they age [27]. In the 45-country data, women's partners were on average 2.4 years older and men's 2.3 years younger, and the gap was smaller in more gender-equal countries [4], the one place where equality clearly moderated a sex difference. In a Finnish sample ($N = 2{,}655$), men's considered age range widened with age, but interest in much younger women was rarely turned into actual sex, because the other side chooses too [28].

F. Online Dating (D3)

Meeting online became the most common way heterosexual US couples meet, overtaking meeting through friends around 2013 [47], so app behaviour now matters for real couples.

On a large US site, desirability formed one shared hierarchy, and men and women both messaged people about 25% more desirable than themselves (26% and 23%) [6]. Men's desirability rose with education and peaked near age 50; women's fell from age 18 and peaked at an undergraduate degree. In six months of messages in one US city (8,259 men, 6,274 women), both sexes messaged the most desirable people regardless of their own standing; women sent four times fewer messages, but their messages were twice as likely to connect, and couple similarity arose mostly from unanswered messages [33]. Feeding estimated preferences into Gale–Shapley matching [48] reproduces observed matches and marriage sorting [7]. Users also screen with a few deal-breakers before weighing anything else [49].

G. The 80/20 Claim (D4)

The claim is that most women compete for the top fifth of men. The best research figure on swipe asymmetry is small: in a conference study of Tinder activity by fake profiles, men matched about 0.6% of the time and women about 10% [34], as reported in secondary summaries. Popular "Gini of likes" figures come from an anonymous blog post and from company numbers quoted in the press; we could not audit them and do not cite them.

The peer-reviewed data tell a different story. Attention is unequal for both sexes and men get fewer replies, but both sexes aim above themselves by about the same amount, women's messages are not limited to a top 20%, and final couples are mostly matched like with like [6], [33]. Even OkCupid's 2009 post, a likely root of the "women rate 80% of men below average" line, reported that women's messaging was only slightly skewed toward attractive men [35]. Attention inequality on one app is not partnering inequality in a population. Verdict: not supported as stated.

IV. Beyond Status

Online arguments about dating go well past money and degrees: casual versus serious dating, height, build, penis size, intelligence, looks, age and race. Table II gives the verdicts on the same scale as Table I. One warning applies to most of it. Much of this evidence comes from small groups of Western students rating photos, figures or questionnaires, so it measures stated or first-impression preferences (D2, or D3 at first contact). Where data on real contacts or couples exist, the effects are usually smaller.

A. Short-Term Versus Long-Term Partners

Sexual strategies theory holds that both sexes pursue separate strategies for casual and committed relationships [50], [79], and stated preferences agree. When 93 US students set minimum standards on 24 traits for four levels of commitment, women were more selective overall, especially on status. Men accepted far lower standards for a sexual partner but were nearly as choosy as women for a long-term one [51]. In mate-budget tasks women treated status as a necessity for a long-term partner, while for a short-term partner both sexes spent first on looks [52], and body shape mattered most for a one-time encounter [53]. In a German community speed-dating study ($N = 382$, ages 18 to 54), both sexes chose mainly on looks and women also on men's education and income. Only 6% of matches led to sex and 4% to a relationship within a year [80].

The ovulation story, that women prefer more masculine men around ovulation, has not held up. Two meta-analyses of the same literature disagree [54], [55]. The largest longitudinal study ($N = 584$, hormone measures) found no link between hormones and a preference for masculine faces [56], and a preregistered study with ovulation tests ($N = 157$) found no shift [57]. Both still found that masculinity counts more in short-term ratings. So context matters and the cycle mostly does not. The stated status preference is mainly a long-term one, and one status weight for every kind of relationship overstates hypergamy for casual dating.

B. Height and Build

Women want a taller partner more than men want a shorter one: in a Dutch student sample ($N = 650$), women were most satisfied with a partner about 21 cm taller, men with one about 8 cm shorter [58]. On a US dating site the effect at first contact was relative to one's own height, and women showed no preference for absolute height [14]. The famous "6'3" gets 65% more messages than 5'7"" comes from a 2006 draft of that work, and the published papers say non-robust earlier results were dropped. Profile heights are also inflated, mostly by men [81]. In 12,502 UK couples, partners' heights correlated at $r = .18$, and the man was not taller in 7.5% of couples against 10.2% expected under random pairing [59]. Random pairing alone would give the "man taller" norm about 90% of the time, because men are taller on average.

For men's bodies, perceived upper-body strength explained over 70% of the variation in rated bodily attractiveness [61]. Women rated muscular men as sexier but less committed and rated moderate muscularity highest [63], and torso shape was the strongest predictor for life-size male figures [62]. We found no study on arm span. The nearest proxy is leg length, where legs about 5% longer than average were rated most attractive [64]. All of this is ratings of photos and figures, not real partner choice.

C. Penis Size

In ratings of life-size figures, larger size raised attractiveness with diminishing returns, about as much as height and less than torso shape [62]. With 3D models, 75 US women preferred about 16.3 cm length for a one-time partner and 16.0 cm for a long-term one [65]. Clinician-measured studies of up to 15,521 men give a mean erect length of 13.1 cm (SD 1.7) [82], though handled models and clinical measurements are not directly comparable. In an online survey of 52,031 heterosexual US adults, 85% of women were satisfied with their partner's size,

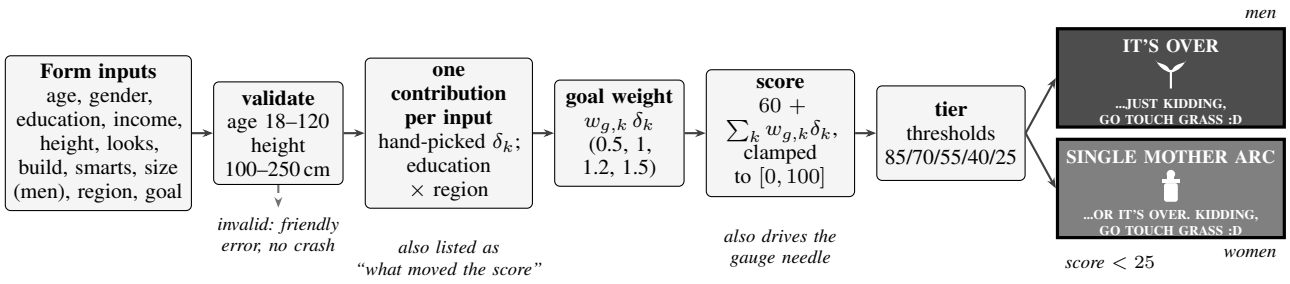

Fig. 3. The Hypergamy Meter pipeline, as implemented in `app/src/model.rs` and `app/src/memes.rs`. Every step is a pure function. The two cards are the lowest-tier memes for men and for women (non-binary users get "IT'S OVER (ALL GENDERS EDITION)"). The weights are illustrative, not estimates.

but only 55% of men with their own [66]. Size worries men far more than it matters to women, and no study links it to actual partner choice.

D. Intelligence

Intelligence ranks near the top for both sexes [3], [4]. Rated desirability of a partner's IQ peaked around the 90th percentile (about IQ 120) and dropped slightly at the 99th [67], and a replication with 214 young adults found the same [68]. Both are stated ratings from one lab. Couples are clearly matched: a meta-analysis of 199 studies gives partner correlations of $r = .44$ for IQ and $r = .55$ for education [69]. Whether intelligence helps anyone find a partner is unclear. In a Scottish cohort born in 1921 ($N = 883$), higher childhood IQ lowered women's odds of marrying by mid-life (odds ratio 0.42 per standard deviation), while the link for men was positive but not significant [70].

E. The Famous Dating-App Numbers

Looks drive first contact for both sexes, a bit more for men [14], [71], and men's messages target younger women, more so as they age [14], [72]. Table III grades the numbers that circulate in the debate. The peer-reviewed ones say that both sexes aim up and that markets split by age and race [6], [14], [75]. The most quoted ones (the Tinder and Hinge "Gini of likes", "women rate 80% of men below average", "6'3" gets 65% more") come from blogs, press retellings or a dropped draft. We found no peer-reviewed or audited estimate of like or swipe inequality on a swipe app. Unequal attention on apps is plausible and fits the messaging studies, but every specific "Gini" or "80/20" number is blog-grade.

F. Race and Ethnicity: Documented Bias

This subsection describes discrimination. It does not rank anyone's worth. On US dating sites both sexes mostly contact people of their own race, and 30 of 31 estimated race effects were negative. A white man was 10% less likely to contact a black woman than a white woman, and a white woman 12% less likely to contact an Asian man than a white man [14]. In replies a racial hierarchy appeared that a college degree did not offset [73]. In 6,070 US profiles, Asian men and black women were the most excluded [74]. A book-length study calls this "digital-sexual racism" [76]. OkCupid's blog charts point the same way, with no decline from 2009 to 2014 by the company's account [78]. In US marriages, black-white intermarriage tripled between 1980 and 2008, while intermarriage with whites stalled for Asians and American Indians [77]. These studies measure bias against people, not anyone's value as a partner, which is why the app in Section VI has no ethnicity input.

V. Explanations

Evolutionary. Different reproductive costs shaped different preferences: women value resources and ambition more, men value youth and looks more [3], [27]. This fits the universality of the stated gap and of the age gap [4], and it predicted the short- versus long-term difference of Section IV [50]. It fits less well the small sex differences once people meet [5] and how fast educational hypergamy reversed.

Social role. The division of labour shapes preferences, so the provider preference should weaken when women earn their own resources [41], [42]. Some cross-national data agree [12], [13], as does the shrinking age gap [4]. The largest replications find little moderation for other traits [4], [11].

Structural (who is available). Whom people marry depends on preferences, third parties and whom they meet [45]. The clearest demonstration is the agent-based model of Grow and Van Bavel [8]. Calibrated on 12 Western European countries for cohorts born from 1921 to 2012, it reproduces both the old hypergamy and the new hypogamy with only two ingredients: a preference for a partner with similar education and a preference for higher earnings. It needs no preference for "marrying up" and no change in preferences over time; the shifting supply of educated men and women does the work. In a stylised form (ours, not their exact specification), a chooser i scores a candidate j as

$$s_{ij} = -\alpha\,|e_i - e_j| + \beta\, y_j, \tag{1}$$

with education e, expected earnings y and fixed weights $\alpha, \beta > 0$. If men outnumber women among graduates, a taste for similarity alone leaves many women with more-educated husbands. Once the balance flips, the same fixed α and β leave many highly educated women with less-educated husbands. Hypergamy then looks like a preference when it is mostly arithmetic. This does not prove that no preference exists. It shows that the marriage pattern alone cannot prove that one does.

TABLE II
VERDICTS BEYOND STATUS, SAME SYMBOLS AND STRENGTH SCALE AS TABLE I.

Claim	Def.		Verdict	Strength	Main sources
Women weight status more for long-term partners; for short-term partners both sexes put looks first	D2	●	exists, in stated preferences	moderate	[50]–[53]
Men lower their standards for casual sex far more than women, but not for a long-term partner	D2	●	exists (stated)	moderate	[50], [51]
Women's taste shifts toward masculine men around ovulation	D2	○	mostly not: meta-analyses disagree, large preregistered studies find no shift	moderate	[54]–[57]
Women want taller men more than men want shorter women	D2, D3	●	exists, stated and at first contact	strong	[14], [58]
Couples follow the "man taller" norm	D1	◐	yes, but only a little more often than chance	strong	[59]
Tall men get far more messages ("6'3" gets 65% more than 5'7"")	D3	?	height counts relative to one's own; the 65% is from an unpublished draft	weak	[14], [60]
Perceived upper-body strength drives ratings of men's bodies	D2	●	exists in photo and figure ratings	moderate	[53], [61]–[63]
Arm span ("wingspan") affects attractiveness	–	?	no direct study; it would mostly be a height effect	none	[64] (proxy)
Penis size affects women's ratings of men	D2	◐	small, about as large as height, diminishing returns	weak to moderate	[62], [65]
Women prefer a larger penis for short-term partners	D2	◐	0.3 cm difference in one study	weak	[65]
Men overestimate how much size matters to women	D2	●	85% of women satisfied vs. 55% of men	moderate	[66]
Intelligence is among the most wanted traits for both sexes	D2	●	exists	strong	[3], [4]
Wanting intelligence has a ceiling near the 90th percentile	D2	◐	found twice, one lab, stated ratings only	weak to moderate	[67], [68]
Partners resemble each other in intelligence and education	D1	●	$r \approx .44$ for IQ, .55 for education	strong	[69]
Higher intelligence helps people find a partner	D1	?	one old cohort, opposite signs by sex	weak	[70]
Looks drive online messages for both sexes, a bit more for men	D3	●	exists	strong	[5], [14], [71]
People rated less attractive adjust whom they approach, men less than women	D3	●	exists	moderate	[33], [71]
Men's messages target younger women, more so as men age	D3	●	exists	moderate to strong	[6], [14], [72]
A measured "Gini of likes" shows extreme inequality for men	D4	?	no peer-reviewed or audited estimate	weak (grade D)	[34]
Racial hierarchies shape who is contacted and answered	D3	●	exists, as documented bias	strong	[14], [73]–[76]
Racial bias in dating is fading	D1, D3	?	intermarriage rising for some groups only	weak to moderate	[77], [78]

The three accounts can all be partly right. In our reading, a modest, cross-cultural sex difference in stated preferences exists, and its size may depend on context. Actual pairing is driven mostly by like-with-like matching and by supply.

VI. THE HYPERGAMY METER

To make the point in the most unserious way we could, we wrote a small desktop app in Rust with the egui toolkit. You enter your age, gender, education, income band, optional height, self-rated looks, build and smarts, region and relationship goal. Men and non-binary users also get an optional size question. You press *Consult the market* and receive a "market verdict". Fig. 3 shows the pipeline and Table IV the weights.

The model. Each input k adds one signed contribution δ_k, and the relationship goal g then multiplies some of them by a goal weight $w_{g,k}$ (Fig. 4). The score is

$$S = \min\Big(100,\ \max\big(0,\ 60 + \textstyle\sum_k w_{g,k}\,\delta_k\big)\Big). \qquad (2)$$

This score is mapped to one of six tiers with lower bounds 85, 70, 55, 40 and 25: from *Top of the market* down to *Clearance aisle (still a bargain)* and, below 25, *Your life is over (statistically, for this joke model)*. The education contribution is also multiplied by a region factor from 0.6 (Northern Europe) to 1.5 (East Asia), meant as a "strength of the marry-up norm". Non-binary users get the midpoint of the woman and man weights, because the model has no data and says so. Invalid ages or heights produce a friendly message, not a crash. The inputs that moved the score are listed, each with a one-line joke.

Meme cards. Each tier has a meme card drawn by the app itself. Only the lowest one is gendered, after the internet's own doom memes. Men get "IT'S OVER" above "... JUST KIDDING, GO TOUCH GRASS :D" with a seedling, women get "SINGLE MOTHER ARC" above "... OR IT'S OVER. KIDDING, GO TOUCH GRASS :D" with a baby bottle, and non-binary users get "IT'S OVER (ALL GENDERS

TABLE III
FAMOUS DATING-APP FIGURES BY EVIDENCE GRADE: A PEER-REVIEWED AND LARGE OR REPLICATED, C CONFERENCE PAPER, DRAFT OR BOOK, D COMPANY BLOG, ANONYMOUS POST OR PRESS.

Figure	Source	Grade
Both sexes message about 25% "up"	[6]	A
Women weight income, men looks, a bit more	[14]	A
Markets split by age and race	[75]	A
Tinder matches: men about 0.6%, women about 10%	[34]	C
6'3" men get 65% more messages than 5'7"	2006 draft, dropped from [14]	C
Women rate 80% of men below medium	OkCupid blog [35]	D
Racial attraction charts, 2009 to 2014	OkCupid blog [78]	D
Tinder "Gini of likes" 0.58	anonymous blog post (not cited)	D
Hinge Gini for men 0.54 or 0.73	press retellings, which disagree (not cited)	D

EDITION)". Every bottom caption takes the verdict back.

The weights are made up. Nothing in Table IV was estimated. The source code says so in capital letters. The weights only copy the *direction* of a few findings. Income moves the score for both genders, a bit more for men, but never dominates, like a stated difference that is real but small [3], [9]. For women the education curve bends down at Master's and PhD, a nod to the reversal of educational hypergamy [2]: anyone who insists on marrying up has fewer "equal or higher" partners. The age curve peaks earlier for women than for men, loosely after online-dating data [6]. Self-rated looks get the largest weight for both sexes [5], [14]. Build helps men more and is capped [61]. Smarts rise to a ceiling and then fall back [68]. Size moves the score by at most one point [62], [66]. The goal weights follow the short- versus long-term findings [51], [52]. The sizes are arbitrary, and the height and goal terms are jokes.

No ethnicity input. The studies in Section IV document discrimination. A score that used race would turn that bias into a personal "result" and repeat it, so ethnicity is neither an input nor an output.

Two examples. The default profile (woman, 28, Bachelor's, middle income, average looks, build and smarts, Turkey/Middle East, long-term) scores $60 + 12 + 4 \times 1.3 \times 1.2 + 2 = 80.24$, *Highly competitive asset*. A 60-year-old woman with a PhD, low income, average looks, build and smarts, East Asia, undecided, scores $60 - 22 - 8 \times 1.5 - 2 - 2 = 22$, and her card reads "SINGLE MOTHER ARC". Four demo profiles (`--demo top`, `niche`, `its-over`, `single-mother-arc`) open the app already scored, and a unit test keeps each in the tier its name promises.

Why it is not science. The meter breaks most of the rules in Sections III to V. It applies group averages to one person, it mixes stated and revealed preferences, it ignores that most couples form like with like [45], [69], [83] and that the other side chooses too [28], [33], and it has eleven inputs, most of them self-rated, and no personality. Group averages hide large overlap and large individual variation [4], [10], so a score for one person carries no information. That is the joke. The app stores nothing and is labelled "for fun only, not science, not advice".

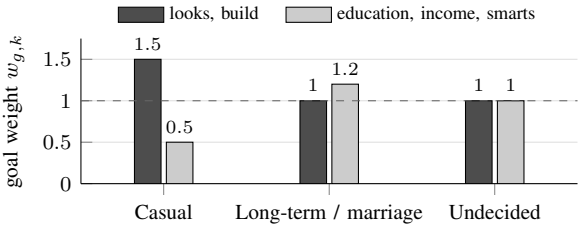

Fig. 4. Goal weights $w_{g,k}$ of the Hypergamy Meter, exactly as in `goal_weight` in `app/src/model.rs`. *Illustrative*: the values are hand-picked. Only their direction follows the short- versus long-term findings [51], [52]. Age, height, size and the goal term itself always have weight 1.

TABLE IV
HYPERGAMY METER CONTRIBUTIONS IN POINTS (HAND-PICKED, NOT ESTIMATED). RANGES SHOW THE LOWEST AND HIGHEST VALUE PER INPUT.

Input	Woman	Man
Age	$+12$ at 25–29; -22 at 50+	$+10$ at 30–34; -10 at 50+
Education[a,b]	$+4$ Bachelor's; -8 PhD	-6 high school; $+6$ Master's or PhD
Income band[b]	-2 low; $+3$ high	-10 low; $+10$ high
Height	-1 to $+1$	-6 under 170 cm; $+7$ at 190+
Looks[c]	-8 below average; $+11$ head-turner	-7 below average; $+10$ head-turner
Build[c]	-1 couch potato; $+2$ gym or statue	-3 couch potato; $+5$ Greek statue
Smarts[b]	0 average, $+4$ smart, $+6$ very smart, $+3$ galaxy brain	
Size	not asked	-1 below average to $+1$
Goal	-2 undecided to $+3$ casual, same for everyone	

Base 60; total clamped to $[0, 100]$; height and size are optional; non-binary users get the midpoint, and the man's size row. [a]Multiplied by a region factor: 0.6 Northern Europe, 0.9 North America, 1.0 Latin America, 1.1 Southern Europe, 1.3 Turkey/Middle East, 1.5 East Asia. [b]Multiplied by 0.5 for a casual goal and 1.2 for long-term or marriage. [c]Multiplied by 1.5 for a casual goal.

VII. LIMITATIONS

This is a narrative review, not a systematic one, and it leans on Western, mostly US and European, data; work on South and East Asia is thin here apart from Japan [37]. Several numbers come from abstracts or secondary summaries rather than full texts: the meta-analytic correlations [5] (from an author copy), the Tinder match rates [34], the OkCupid figures [35] (an archived company blog) and the gender-equality results of [12] (from a press release). Beyond status, [58], [64], [67], [70] and parts of [62] are read from secondary summaries, and [76] from its publisher's description. The breadwinner replication [26] is a working paper, and [60] is a preprint. Most evidence beyond status comes from students rating photos, figures or questionnaires, not from real partner choice. Dating-site studies use self-selected users, and fake-profile experiments test first impressions only. Income is measured after marriage, which

itself changes earnings. Evidence on same-sex couples is thin [38]–[40]. Fig. 2 is a schematic, and the app's weights are invented.

VIII. Conclusion

Is hypergamy real? Partly, and it depends which one you mean. Women's stated preference for earning prospects is real, cross-cultural and small per trait. Women still tend to partner with men who earn more and are a few years older. Educational hypergamy was real and has mostly reversed, and supply explains the reversal without any change in what people want. The claims that power the online version (status is all that matters, only women aim up, most women share the top fifth of men) are not supported. Beyond status, the sexes differ most in what they say they want from a long-term partner and least for a casual one. Height, build, penis size and intelligence count in ratings, mostly by small amounts. The most viral dating-app numbers are blog-grade, and the racial patterns on apps are discrimination, not a measure of anyone's worth. The strongest pattern in the data is the least dramatic one: people mostly pair with people like themselves. If the Hypergamy Meter ever tells you your life is over, believe the bottom caption.
